A NATIONAL DATA SYSTEM ON P INPUTS AND BALANCES ESTABLISHED BY FERTILIZER INDUSTRY

Philippe EVEILLARD

UNIFA, French Fertilizer Industry Association

peveillard@unifa.fr

► UNIFA - Paris, France

- National fertilizer industry association
- 50 producers (lime, fertilizers, organic products, biostimulants)
- Official mandate to collect national statistics on fertilizer deliveries
- Updates since 1989 P, K and Mg total input to ag. soils and P, K and Mg balance

I. Why using P balance as an indicator?

1. P balance is easy to calculate
2. Limited P transfer from soil to air or water
3. Positive P balance = increase of P stock in soil
4. Negative P balance = decrease of P stock
5. This indicator can be used at field, farm and regional scale (22 régions in France)

II. Simple methodology of P balance

Total INPUT – Total OUTPUT = P balance

INPUT =

Mineral and organic fertilizers (including imports from B and NL)

Total excreta from farm animals

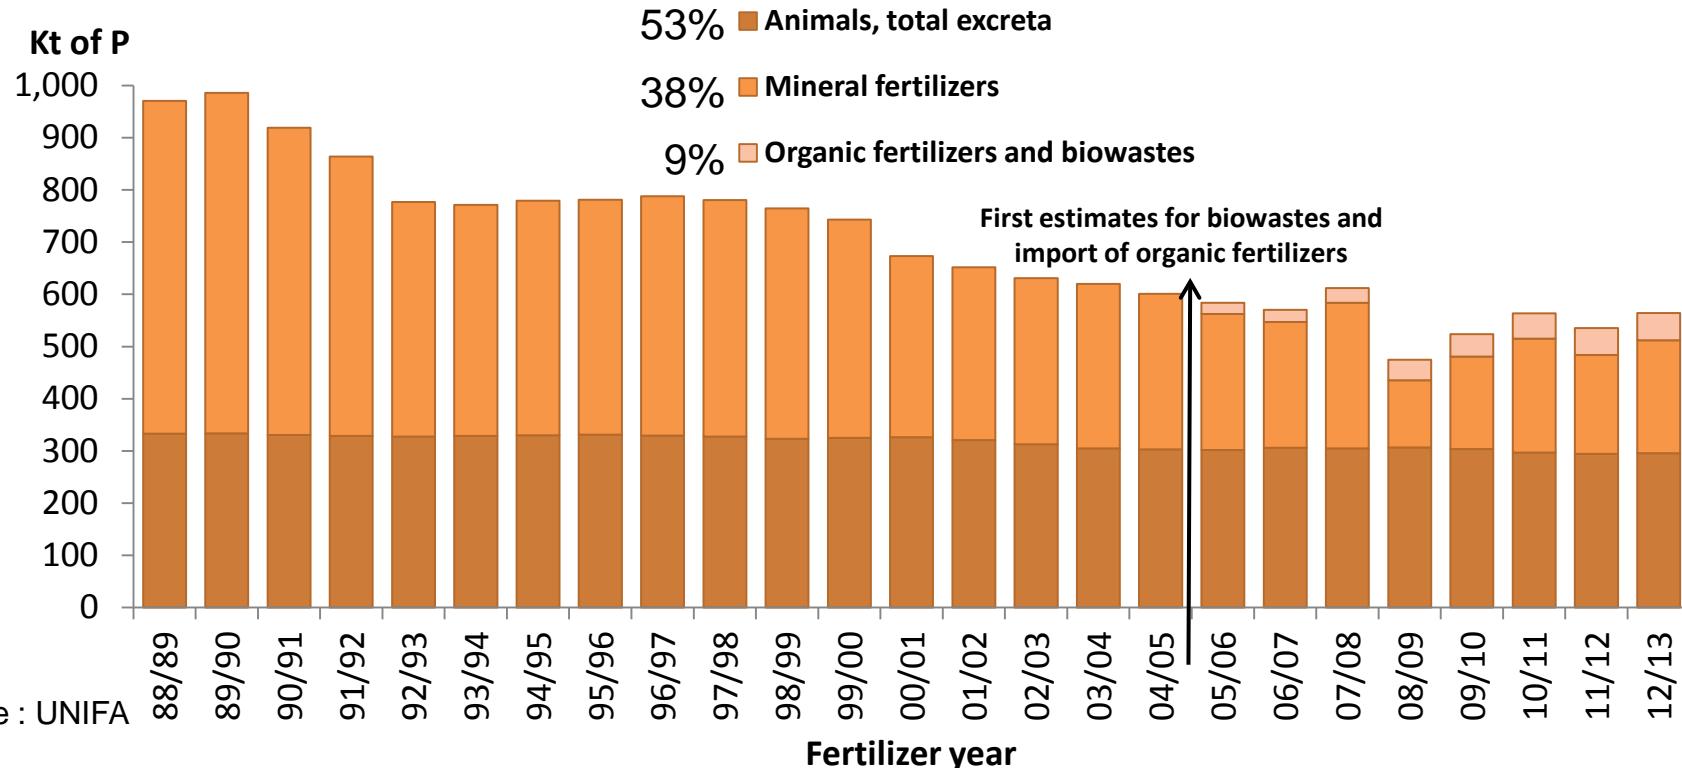

Biomass: composts, sludges, digestates....

OUTPUT =

Crop production (annual national statistics) except for cereal straw

Grass both yielded and grazed (calculation according to number of ruminants)

III. Decrease of P input, a long term trend

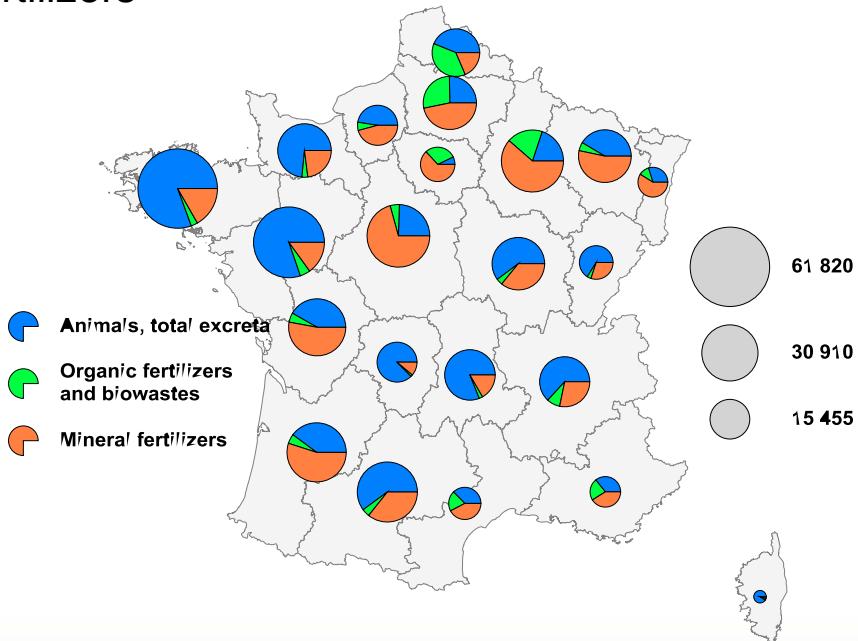

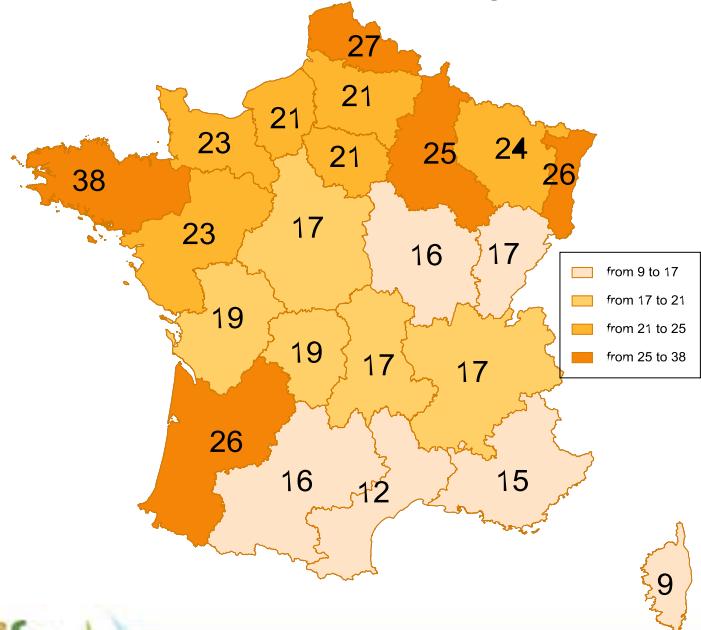

Source : UNIFA

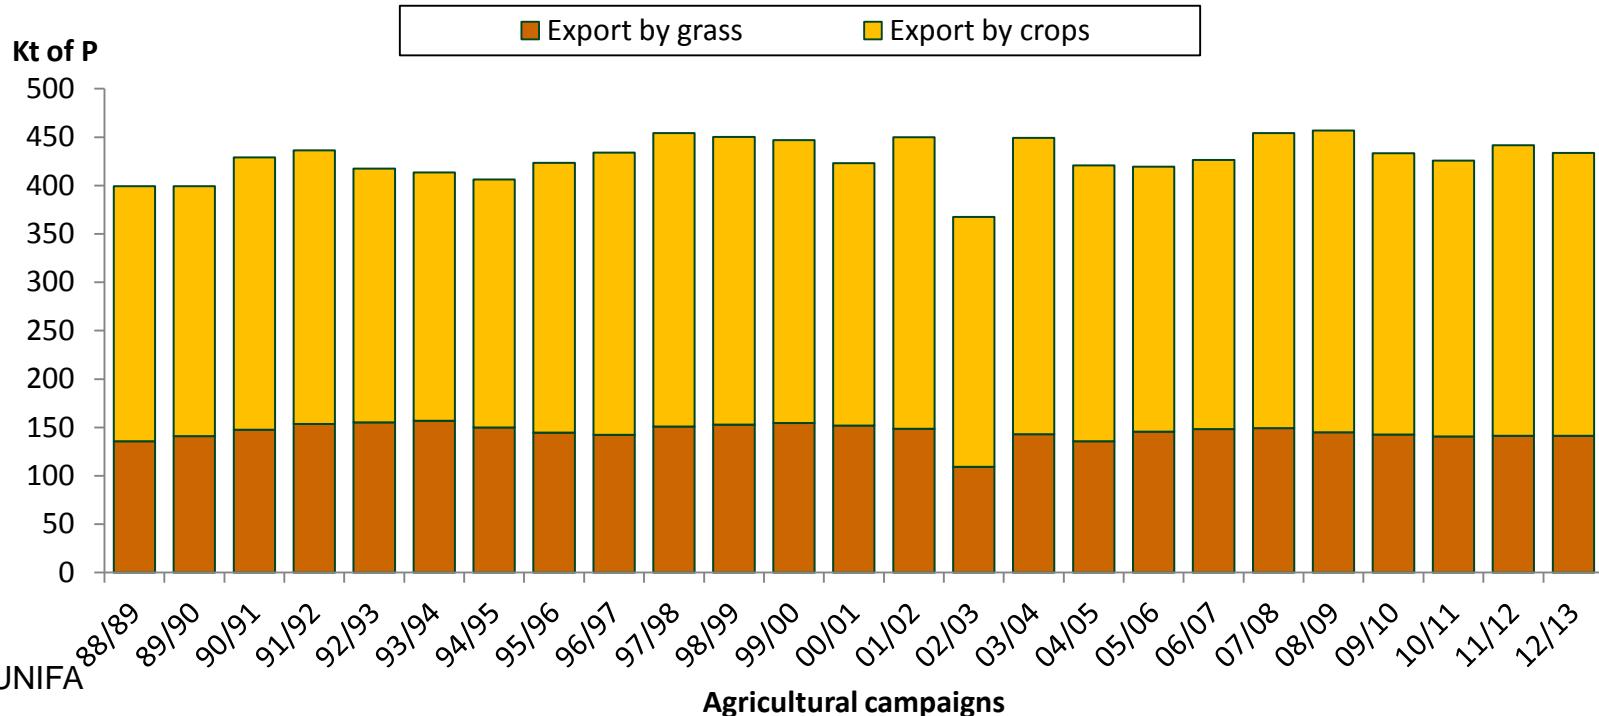

III. P in animal excreta, a major contributor

Total input in Kg P/ hectare of ag. land

France: 21 kg P /ha (Last 3 fertilizer years 2011-2013)
of which 8 kg P in mineral fertilizers

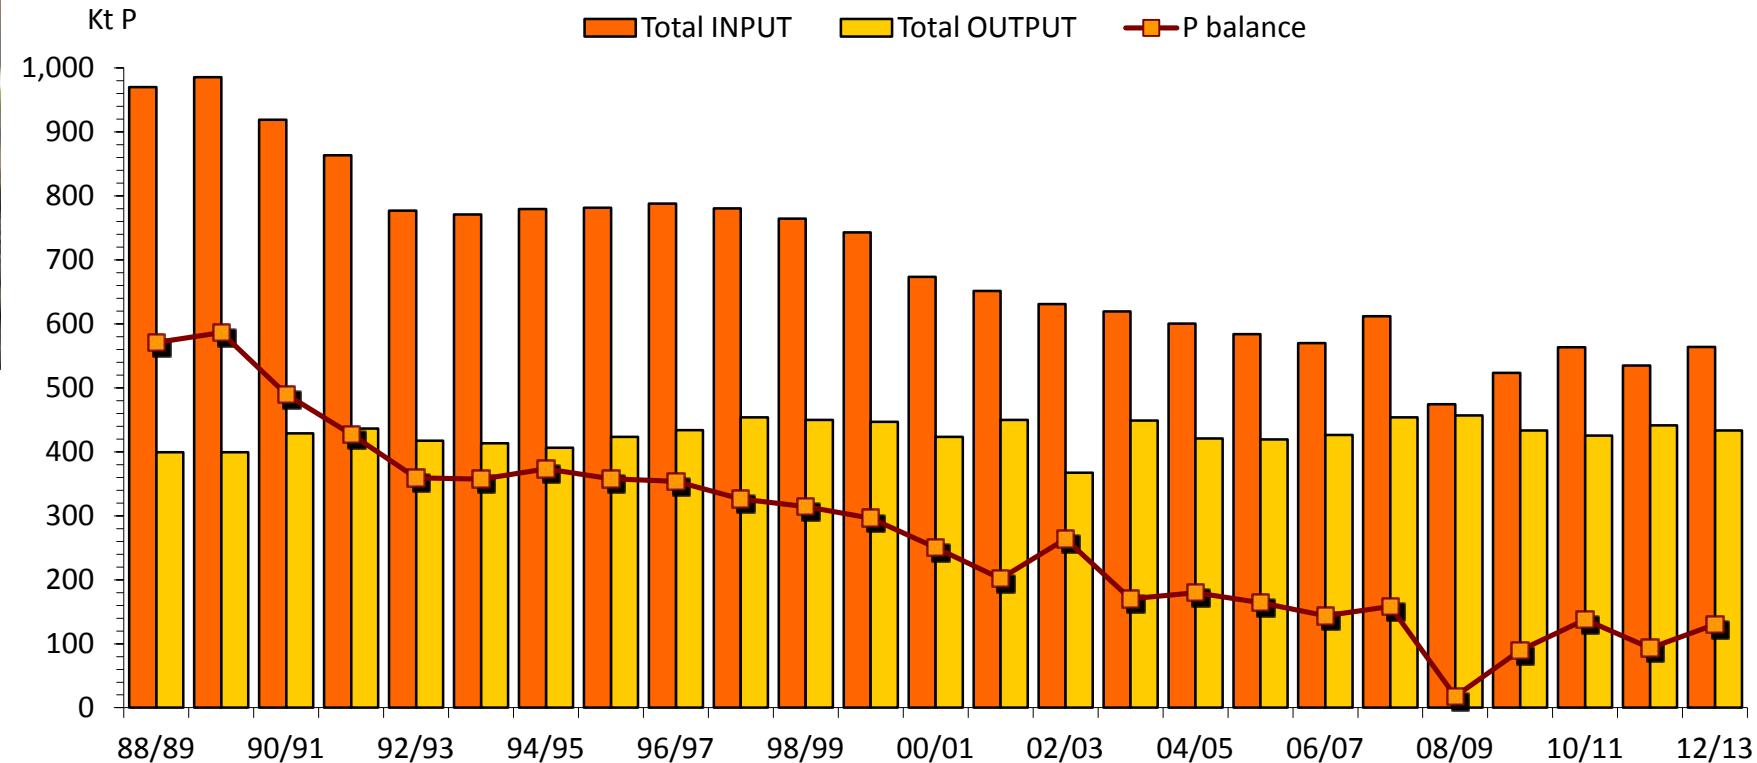

IV. Slight increase of P export in crops and grass

Source : UNIFA

V. P balance close to equilibrium

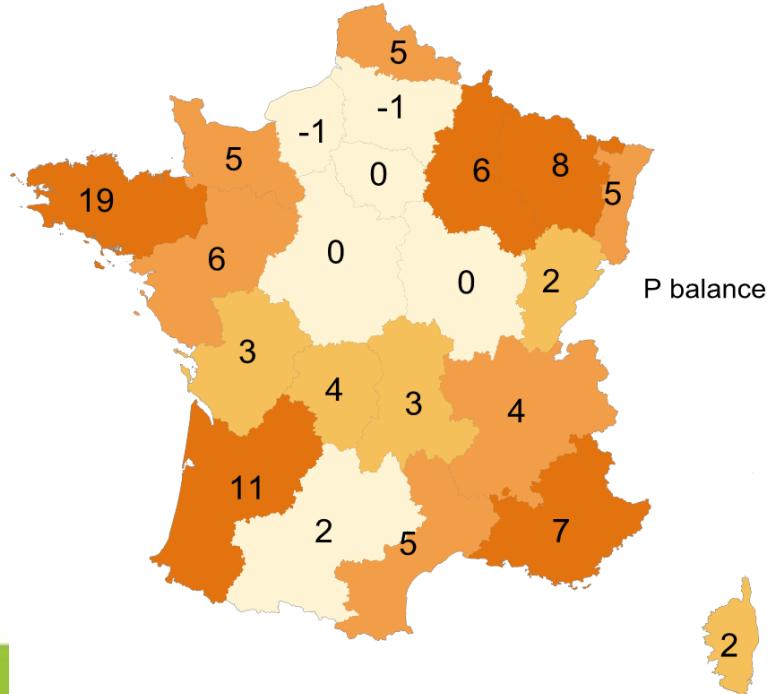

Source : UNIFA

V. Contrasted P balance across regions

Input – Output in Kg P/ hectare of ag. land

4.4 kg P /ha (fertilizer years 2011-2013)

Conclusion:

A low 4.4 kg P/ha balance due to reduced P input

 42% less total P input since 1988/89, mainly mineral fertilizers

 9% more total P output since 1988/89, mainly crops

 78% reduction of P positive balance

P balance is negative or low in 7 regions (< 2,2 kg P/ha) with limited cattle and large cereal production

P balance is positive in 15 other regions (> 2,2 kg P/ha) with more animal production

Conclusion (2):

Recycling of P in manure and biowaste is a key issue

- **P in animal excreta tends to decrease:** less animals, less P in the diet (phytase, lower P recommended) and in the manure
- **P in biowastes is important** but cannot compensate for the decrease of P input
- **Risk of decreasing P soil fertility** in regions exporting cereals
- **More effort to balance P fert.** at field, farm and regional scale
